This report reflects cases that have been publicly reported up to 2020-10-29. Note that data from the CORES system were not available for cases from Toronto Public Health with a publicly reported date of 2020-08-13, and data from iPHIS were not available for cases from Algoma Public Health, Brant County Health Unit, Chatham-Kent Public Health, City of Hamilton Public Health Services, Niagara Region Public Health, Peterborough Public Health, Simcoe Muskoka District Health Unit, Southwestern Public Health, Public Health Sudbury & Districts, Timiskaming Health Unit, and Windsor-Essex County Health Unit with a publicly reported date of 2020-08-19; as such, estimates and figures reflecting or incorporating these health units will be impacted for these dates.
This report includes the most current information available from CCM and other local case management systems (CCM plus).

Full French translation is available upon request.

Due to data availability related to the transition to the Public Health Case and Contact Management Solution (CCM), the timeliness figure related to time from symptom onset to specimen collection is currently unavailable for case reported dates after 2020-07-16.

**Purpose**

This report provides a summary of the regional case counts of COVID-19, likely source of acquisition, and the timeliness of testing and investigation in Ontario. These regional measures provide important information to support and monitor re-opening across Ontario.

A brief description of the measures included in this report are summarized below. Additional details are outlined in the Methods section, found toward the end of this document.

**Case count**

We measured the daily number of COVID-19 cases according to the date a case was publicly reported (i.e., the date the public health unit [PHU] reported the case to Public Health Ontario [PHO] plus one day to account for the delay in public reporting) and produced an epidemic curve using these counts over time. Examination of these epidemic curves can be used to determine the current trajectory of the epidemic in each region.

**Reproduction number**

The reproduction number is the average number of secondary cases of infection generated by each person infected with COVID-19. A reproduction number greater than one means that the epidemic is growing in a region, while a reproduction number less than one means the epidemic is coming under control in a region.

**Likely source of acquisition**

COVID-19 cases have been examined to determine whether a case travelled, was associated with an outbreak, was a contact of a case, had no known epidemiological link (sporadic community transmission), or where information was pending or missing. Tracking the number of cases with no known epidemiologic link provides insight into how well we are able to ascertain where cases are coming from and may reflect the effectiveness and timeliness of the contact tracing process, as well as indicate adherence to public health guidance by individuals who are asked to isolate.

**Timeliness of case presentation, testing, and investigation**

To halt transmission, it is crucial that potential cases are rapidly identified, tested, reported, and managed (which includes contact tracing). We examined three timeliness metrics. First, the proportion of cases that have a specimen collected for testing within 2 days of symptom onset. Second, the proportion of cases that had a positive result reported to the PHU within 1 day of specimen collection.
Third, the proportion of cases for which case management began within 1 day of a positive result reported to the PHU.

Methods

- The data for this report were based on:
  - Information extracted from the Ontario Ministry of Health (Ministry) integrated Public Health Information System (iPHIS) database for Toronto Public Health as of 4 p.m. on the day prior to this report.
  - Information successfully uploaded to the Ministry from Local Systems: Toronto Public Health (Coronavirus Rapid Entry System) CORES, The Ottawa Public Health COVID-19 Ottawa Database (The COD) and Middlesex-London COVID-19 Case and Contact Management Tool (CCMtool) as of 2 p.m. on the day prior to this report.
  - Information successfully uploaded to the Ministry from the Public Health Case and Contact Management Solution (CCM) for all other PHUs as of 1 p.m. on the day prior to this report.
  - The date variable used in the figures for the epidemic curve and the reproduction number throughout this report refers to the date that a case first appeared in the compiled data set + 1 additional day. This corresponds to the “public reporting date” of each case at the provincial level.
  - In order to account for certain instances when there were long lags between when a case’s specimen was collected and when their data was entered into CCM, iPHIS, CORES, The COD, or CCMtool, we replaced the public reporting date with the specimen collection date + 3 days (the mode of the distribution from specimen collection to public reporting date). This replacement was made for cases whose delay between specimen collection and case creation was between 7 and 90 days.
  - In rare circumstances when this delay was more than 90 days, we did not make the date replacement.
  - The date variable used in the figures for the likely acquisition and the timeliness metrics refers to the case reported date, which is the date the case was reported to the public health unit.
  - Due to smaller case counts, we have combined the North West and North East regions into a single region in this report.
  - The PHUs were categorized into regions as follows:
    - Toronto: Toronto Public Health
    - Central East: Durham Region Health Department, Haliburton, Kawartha, Pine Ridge District Health Unit, Peel Public Health, Peterborough Public Health, Simcoe Muskoka District Health Unit, and York Region Public Health
    - Central West: Brant County Health Unit, City of Hamilton Public Health Services, Haldimand-Norfolk Health Unit, Halton Region Public Health, Niagara Region Public Health, Region of Waterloo Public Health and Emergency Services, and Wellington-Dufferin-Guelph Public Health

• Northern: Northwestern Health Unit, Thunder Bay District Health Unit, Algoma Public Health, North Bay Parry Sound District Health Unit, Porcupine Health Unit, Public Health Sudbury & Districts, and Timiskaming Health Unit

• South West: Chatham-Kent Public Health, Grey Bruce Health Unit, Huron Perth Public Health, Lambton Public Health, Middlesex-London Health Unit, Southwestern Public Health, and Windsor-Essex County Health Unit

• GTA health units include: Durham Region Health Department, Peel Public Health, Toronto Public Health, and York Region Public Health.

• With the exception of the time from case reported date to investigation start date, orientation of case counts by geography is based on the diagnosing health unit (DHU). DHU refers to the case’s public health unit of residence at the time of illness onset and not necessarily the location of exposure. For the time from case reported date to investigation start date, responsible public health unit was used in order to align with the process for case management. Cases for which the responsible health unit was reported as the Ministry of Health (MOH) (to signify that the PHU is not responsible for case management, such as cases that are not residents of Ontario) have been excluded from the analyses.

• Epidemic curve: smoothed epidemic curves were estimated using generalized additive models of the daily number of cases.

• Reproduction number: the reproduction number was measured using the EpiEstim package in R.\(^1\) The procedure uses daily reported case counts and a 7-day rolling window for estimation. The mean serial interval was set at 4.5 days with a standard deviation of 2.5 days, as adapted from published estimates.\(^2,3\) EpiEstim uses a Markov Chain Monte Carlo sampling procedure, and the median represents the middle of the distribution of most probable values of the reproduction number. The reproduction number of a region was only calculated when there were at least 12 cases in that region in the last 7 days.

• Likely source of acquisition is determined by examining the epidemiologic link and epidemiologic link status fields in CCM and local systems. If no epidemiologic link is identified in those fields the risk factor fields are examined to determine whether a case travelled, was associated with an outbreak, was a contact of a case, had no known epidemiological link (sporadic community transmission) or was reported to have an unknown source/no information was reported. Some cases may have no information reported if the case is untraceable, was lost to follow-up or referred to FNIHB. Cases with multiple risk factors were assigned to a single likely acquisition source group which was determined hierarchically in the following order:

  • For cases with an episode date on or after April 1, 2020: Outbreak-associated > close contact of a confirmed case > travel > no known epidemiological link > information missing or unknown.
• For cases with an episode date before April 1, 2020: Travel > outbreak-associated > close contact of a confirmed case > no known epidemiological link > information missing or unknown.

• Data for the three days prior to the extract date are not shown for this graph due to lags in data entry.

• Timeliness of reporting: smoothed curves were estimated using generalized additive models of the proportion of cases that were reported within the stated time frame. The dots in the graph represent the individual proportions for a given reported date. The duration elapsed from reporting to investigation was only measured from May 1st onwards, as this is the date that the directive to enter investigation start date was issued. Cases with missing or pending dates have been excluded from the denominator in this analysis.

• For the time from case reported date to investigation start date, cases with a disposition status of referred to the First Nations and Inuit Health Branch (FNIHB), lost to follow up, or untraceable were excluded from the analyses.

• If there were no cases within 7 days of the case reported date, the smoothed curve for the proportion meeting the target is not shown.

• Data for the three days prior to the extract date are not shown for this graph due to lags in data entry.

Limitations

• This report includes confirmed cases of COVID-19 as per the Ontario Ministry of Health case definition. However, this report excludes persons with a positive detection of serum/plasma immunoglobulin G (IgG) antibodies to SARS-CoV-2, which was added to the confirmed case definition on August 6, 2020. Case detection is strongly influenced by the provincial testing strategy, which may also influence the time elapsed between various steps in the testing and notification process.

• CCM and CCM plus (which includes CCM, iPHIS, CORES, The COD, and COVID-19 CCMtool) are dynamic disease reporting systems, which allow ongoing updates to data previously entered. As a result, data extracted represent a snapshot at the time of extraction and may differ from previous or subsequent reports.

• The data only represent cases reported to public health units and recorded in CCM plus. As a result, all counts will be subject to varying degrees of underreporting due to a variety of factors, such as disease awareness and medical care seeking behaviours, which may depend on severity of illness, clinical practice, changes in laboratory testing, and reporting behaviours.

• The public reporting date lags the infection date; as such, public reporting dates likely represent infections that occurred approximately 10 days earlier.

• For reproduction number analyses, all cases since initial importation were presumed to be locally transmitted. Further, the estimates of the reproduction number are influenced by the choice of serial interval. As such, the reported estimates in the analysis are subject to change as additional data on the estimated serial interval are published.
The epidemic curves in this report will not align with the curves provided in other reports due to the date chosen. In monitoring trends over time, the public reporting date was specifically chosen in order to identify early signals of increasing cases, which is challenging when using episode date or reported date due to lags in data entry and therefore the need for caution when reviewing case data for more recent days. As such, numbers from the epidemic curve should not be compared between this regional report and the daily/weekly epidemiologic summary.

Public Health Ontario

Public Health Ontario is an agency of the Government of Ontario dedicated to protecting and promoting the health of all Ontarians and reducing inequities in health. Public Health Ontario links public health
practitioners, front-line health workers and researchers to the best scientific intelligence and knowledge from around the world.
