Review of “Early dynamics of transmission and control of 2019-nCoV: a mathematical modelling study”

One-Minute Summary

- This study describes a mathematical transmission model based on cases in Wuhan, cases elsewhere in China, and internationally exported cases, combined with international flight pattern data.

- It estimated 29,500 (14,300 to 85,700) symptomatic 2019-nCoV cases in Wuhan on Jan 23, 2020.

- The estimated median daily reproduction number (average number of secondary cases from an infected individual on each day) varied between 1.6 and 2.9 between mid-December, 2019 and Jan 23, 2020 (when travel restrictions were introduced).

- Based on the median reproduction number prior to travel restrictions, the study estimates that a single introduction of 2019-nCoV would have a 20-28% probability of causing a large outbreak; three infections result in a 50% chance of an outbreak.

Additional Information

- The model assumed that the outbreak commenced with one case on December 2, 2019.

- The number of confirmed compared to modelled cases was concordant in the 20 countries that were most connected to China, except for the USA, France and Australia, which had more confirmed cases than modelled cases.

- It may still take several introductions of cases for an outbreak to establish outside Wuhan. The authors note that this highlights the importance of rapid case finding, and subsequent isolation to reduce the chances of onwards transmission.

PHO Reviewer’s Comments

- Note that this study has not yet been peer-reviewed.
