## One-minute summary

- Using air travel volume data from Wuhan to international destinations, the authors **predicted expected case counts** and 95% prediction intervals (PI). They also **identified locations that might not be identifying imported cases**.
- As of Feb 4, 2020, most international 2019-nCoV cases have been linked to travel from Wuhan, **underscoring the importance of air travel volume** in the risk of cases outside China.
- There was a **positive correlation** between the daily number of air passengers arriving from Wuhan and the case counts in destinations outside mainland China.
  - Locations exceeding the 95% PI, including **Germany, Canada and India**, could be interpreted as having higher capacity to detect cases and/or more connection with Wuhan than captured by daily air travel volume. Local transmission, as in the case of Germany, could also increase case counts to exceed the 95% PI.
  - Locations with case counts on or under the lower bound of 95% PI, including **Indonesia, Cambodia and Thailand**, suggest the potential for undetected cases.

## Additional information

- The authors recommend that outbreak surveillance and control capacity be strengthened in locations below the 95% PI to ensure proper case detection.

## PHO reviewer’s comments

- This article has not been peer-reviewed.
- This analysis was run based on data from February 4, 2020, and the results may become less accurate as the outbreak develops over time.
